

Heat Index

From the user, we are given an air temperatures (T) and a relative humidity (rh).

If the air temperature is given in degrees Celsius ($^{\circ}\text{C}$), we must convert the temperature value to degrees Fahrenheit ($^{\circ}\text{F}$).

To do this check out the temperature conversion formula at:

<http://www.srh.noaa.gov/elp/wxcalc/formulas?tempConvert.pdf>

Then, we can calculate the heat index with this complex formula:

$$\begin{aligned}Index_{heat} = & -42.379 + (2.04901523 \times T) + (10.14333127 \times rh) \\& - (0.22475541 \times T \times rh) - (6.83783 \times 10^{-3} \times T^2) \\& - (5.481717 \times 10^{-2} \times rh^2) + (1.22874 \times 10^{-3} \times T^2 \times rh) \\& + (835282 \times 10^{-4} \times T \times rh^2) - (1.99 \times 10^{-6} \times T^2 \times rh^2)\end{aligned}$$
